Key words: primate nutrition; soybean hulls; corn cob

## INTRODUCTION

The diets of free-ranging orangutans are high in structural cell wall material, which comprises the fiber fraction in plants [Hamilton and Galdikas, 1994]. Microbial populations residing in the hindgut accomplish fiber digestion via fermentation. Animals use volatile fatty acids, end products of fiber fermentation, as a source of energy. Readily available produce items contain small amounts of fermentable fiber [Schmidt et al., 1999]. Commercially manufactured primate biscuits are limited in the amount of fiber they contain due to restrictions in the manufacturing method. Many feeds, used in the livestock industry, are high in fiber, but are generally not palatable to primates. Gels may be an effective tool to deliver high fiber ingredients to primates in a palatable form. Palatability trials were successful as the orangutans readily accepted the gels.

## MATERIALS AND METHODS

Four different trial diets were fed to captive orangutans in this study each consisting of an experimental gel-diet at $67 \%$, fruit at $15.6 \%$, vegetables at $6.2 \%$ and leafy greens at $11.2 \%$ by weight on an as fed basis. Produce currently fed to primates does dilute the total dietary fiber. However, eliminating it would not be representative of a typical zoological diet and therefore was not considered an option for this project. The trial diets differed in the type of experimental gel fed. The gels differed in neutral detergent fiber content (NDF) and the fiber source; hence the trial diets were identified by the type of gel included. The control gel (Diet D), consisted of a ground primate biscuit in the gel matrix with 30\% NDF. The second diet (Diet A) used soybean hulls as $66 \%$ of the gel matrix by weight with $50 \%$ NDF. The third (Diet B) and fourth (Diet C) diets used ground corn cob
as the fiber source at 50 and $65 \%$ by weight resulting in $50 \%$ NDF and $60 \%$ NDF, respectively. A primate biscuit digestibility trial was also conducted to determine if the gel matrix altered digestibility of the diets in comparison to the biscuit. The amount of food offered daily per orangutan was equivalent to $1 \%$ of their bodyweight on a dry matter basis. Dry matter of each experimental gel and as an average for the produce across all categories is approximately $15 \%$. Each gel diet was fed for a period of eight days prior to the three-day collection period. The animals were individually housed during the collection periods and all fecal matter was collected every 4 h , except between 2300 and 0700 when the apes are normally asleep. Orts were collected the following morning. Food samples, orts and feces were analyzed for dry matter, NDF, crude protein (CP) and ash. Differences in digestibility and volatile fatty acid formation between different fiber types and fiber levels were calculated.

## RESULTS

As can be seen in Tables 1-2, increasing NDF levels in the gel led to increased NDF intake by the animals, with an exception for the male with Diet A where intake was poor. As NDF intake increased, dry matter digestibility of the diets decreased for only the highest NDF diet (Table 3). Digestibility of CP and OM for Diets $A$ and $B$ were higher for the male than the female; this may be due to decreased intake, increased retention time in the gut and an increased capacity for fiber fermentation in the hindgut of the male orangutan.

## CONCLUSIONS

Orangutans were capable of extensive fiber digestibility in diets containing $60 \%$ NDF. The gel matrix did not appear to affect digestibility when compared to the biscuit digestibility trial. Total volatile fatty acid formation (Tables 4-5) increased as fiber intake increased, reflecting the ability of the orangutan to ferment the fiber types offered to them in this study. There was no apparent change in stool form. This study will be continued in three more orangutan pairs to complete a latin square for each sex.
